**Definition:** A wound is an injury to the skin. Wounds can be classified as acute or chronic. Acute wounds follow a systematic approach to healing. (1) These steps include hemostasis, inflammation, formation of granulation tissue, and scar remodeling. (2,3) The progression of wound healing in chronic wounds is delayed or impaired. (1,2) Chronic wounds can be classified as vascular injuries (such as venous or arterial ulcers), pressure ulcers or diabetic wounds. Characteristics of chronic wounds include prolonged inflammation of the wound bed and delayed healing. (3)

**Pathophysiology:** The initial stages of wound healing include hemostasis and inflammation. In the hemostasis phase, platelets and other clotting factors are activated to control bleeding at the site of the wound. Once the clot is formed, leukocytes, fibroblasts, keratinocytes and endothelial cells migrate to the wound site. The release of clotting factors and leukocytes help to initiate the inflammatory phase. Cells that migrate to the wound during the inflammatory phase help to rid the site of debris and harmful bacteria. The proliferative phase consists of the formation of granulation tissue and restoration of the vascular system. (3) The work of fibroblasts result in the production of new connective tissue which forms a matrix for the wound. (4) During the scar formation phase, remodeling of the wound matrix leads to contraction of the area. Scar formation results from the apoptosis of fibroblastic cells. (3)

There are three different types of wound healing. Healing by primary intention occurs most often in surgical wounds. The wound edges in this type of healing are closed by sutures, staples or glue which results in less granulation tissue and scar formation. Healing by secondary intention results when wound edges are not approximated. Granulation tissue fills the wound which results in healing. This type of healing occurs in chronic wounds such as pressure ulcers. Wounds healing by tertiary intention have a purposefully delayed primary closure due to complications. (4)

**Etiology:** Wounds can have many different etiologies. All wounds are considered acute at occurrence. Acute wounds can result from surgical incisions, accidents, burns, and trauma. Wounds become chronic when wound healing does not follow the expected stages and/or is prolonged. (6) It is imperative to determine the etiology of the wound in order to ensure proper healing. If able, causative agents should be removed. This is important not only for wound healing but to also prevent recurrence. (6)

**Inclusion Criteria**
- All TCH patients with acute and chronic wounds

**Exclusion Criteria**
- Major Burns

**Diagnostic Evaluation**
A comprehensive initial assessment including a detailed health, medical and social history should be completed. (7)

**History: Assess**
- Etiology of wound

**Physical Examination:**
A focused physical examination should include assessment for/of: (7)
- Wound characteristics including measurement and volume
- Impairments in perfusion or sensation
- Systemic infection
- Vascular impairment if the wound is located on an extremity
- Nutritional deficits
- Pain related to wound
- Risk of developing additional wounds

**Prevention**

**Pressure Ulcers**
- All patients should have a pressure injury risk assessment completed.
  - The Braden scale should be used in adults greater than or equal to 21 years of age.
  - The Braden QD scale should be used in infants and children from 3 weeks to 21 years of age.
  - The Neonatal Skin Condition Scale should be used in neonates up to 43 weeks gestational age.
- Individuals at high risk for pressure injury development include: (7)
  - Patients with a history of trauma
  - Patients with spinal cord injuries
  - Patients with congenital acquired mobility and sensation impairments such as spina bifida, cerebral palsy and multiple sclerosis
  - Patients with a fractured hip
  - Acutely ill patients
  - Patients with diabetes
  - Patients in critical care
  - Patients with surgical operative time greater than four hours
  - Patients with a history of pressure injury
- Utilize a support surface that redistributes pressure and reduces shear for prevention of pressure ulcers. (7)

**Bed Support Surface**
- Beds with low-air-loss features can be used for prevention in a high risk patients and treatment in patients with Category/Stage III and IV pressure ulcers.
- Mattresses and overlays with alternating pressure features can be used for prevention in low risk patients or for treatment in patients with Stage I or II pressure ulcers.
Seating Support Surface
- To determine the most appropriate seating support surface, consult a seating specialist if sitting is unavoidable.
- Consider a seating cushion that redistributes pressure away from ulcer.
- Careful selection is necessary when evaluating the use of alternating pressure seating devices. The benefit of off-loading pressure should be weighed against the risk of shear and instability when sitting for the patient.

Evidence Supports
- Continue the use of the Braden Scale for pressure injury risk assessment in adults greater than or equal to 21 years of age. (7,20) – Strong recommendation, low quality evidence
- Utilize the Braden QD scale for pressure ulcer risk assessment in infants and children from 3 weeks to 21 years of age. (7,20) – Strong recommendation, low quality evidence
- Utilize the Neonatal Skin Condition Score to assess pressure injury risk in neonates up to 43 weeks gestational age. (7,20) – Strong recommendation, low quality evidence
- Consider the use of negative pressure wound therapy in patients with wounds healing by secondary intention with the following clinical concerns. (7,19,21-41) – Weak recommendation, low quality evidence
  - Large painful wound with a copious amount of exudate
  - Failed treatment with traditional dressings
  - Contraindication to treatment with traditional dressings
  - Need for a bridge to surgical wound closure
- Consider iodine dressings for wounds with stable eschar and/or wounds requiring dry wound healing. (7,20,36,38,42-46) – Weak recommendation, low quality evidence
- Consider the continued use of silver-based products for infected wounds and wounds suspected of infection. (7,19,36,38,42,44,47-55) – Weak recommendation, low quality evidence
- Use honey in patients with necrotic wounds and burns. (7,19,36,43,56-58) – Strong recommendation, moderate quality evidence
- Patients should be followed up for wound care by a trained multidisciplinary group of experts in wound and ostomy care. (99-61) – Strong recommendation, very low quality evidence

Evidence Against
- Iodine based dressings should not be used in neonates. (36) – Strong recommendation, low quality evidence
- Whirlpool should not be routinely used for debridement of wounds. (7,19,36,70-78) – Strong recommendation, very low quality evidence

Evidence Lacking/Inconclusive
- Consider the use of home health services for wound care in patients with the following criteria. – Consensus recommendation
  - Severe wound requiring negative pressure wound therapy or complicated treatment methods
  - Psychosocial concerns
  - Concerns related to access to follow-up including supplies
  - Need for DME care coordination
- Outpatient treatment is preferred for wound care however, inpatient treatment can be considered if there are concerns about availability of supplies needed for wound care in the home environment. Patients should be discharged with the best options for wound care covered by financial provider. – Consensus recommendation

Critical Points of Evidence*

*NOTE: The references cited represent the entire body of evidence reviewed to make each recommendation.
Condition-Specific Elements of Clinical Management

**General:** Outpatient treatment is preferred for wound care. Inpatient care may be needed depending on individual patient acuity, and access to supplies in the home environment.

**Treatment Recommendations:**

**Initial Assessment and Care**

- Assess wound and document characteristics
- Cleanse wound with sterile saline.
- Redistribute pressure if necessary.

**Detailed Assessment by Trained Wound Care Provider**

- Document characteristics of wound including wound measurement and volume
- Assess for pain with and without treatment, signs of infection and percent of devitalized tissue
- Determine etiology of wound
- Initiate appropriate consults
- Ensure nutritional assessment complete and initiate plan to correct any nutritional deficiencies

**Wound Bed Preparation – Debridement**

- Necrotic tissue should be debrided using appropriate methods.
- Dry gangrene and eschar should be left in place until tissue is revitalized
- Surgical debridement should be utilized for infected wounds and/or wounds with a large amount of necrotic tissue.
- Autolytic debridement with appropriate dressings should be used should for wounds without an urgent need for removal of devitalized tissue or infection.
- Whirlpool debridement is discouraged in most cases.

**Infection**

- Suspect wound infection when the following signs are noted: 
  - Lack of sign of healing for two weeks
  - Friable granulation tissue
  - Increased pain, redness, heat or exudate
  - Infectious change in exudate characteristic (eg. foul odor, purulent)
  - Increase in the amount of necrotic tissue
  - Pocketing and/or bridging in the granulation tissue.
- If infection is suspected, a tissue biopsy is the preferred method for obtaining a culture. If a tissue biopsy is not available or appropriate, utilize the Levine technique to culture the wound.
  - Levine Wound Culture Technique –
    - Cleanse the wound with sterile saline
    - Rotate the end of the swab over a 1cm² area for 5 seconds with enough pressure to extract exudate from wound tissue.
- If osteomyelitis is suspected, obtain an x-ray of the affected area. If additional imaging is needed, obtain a MRI.

**Dressing Selection**

There are many different dressings available for wound care. See Wound Care Product Glossary (page 4) for suggested dressings based upon wound characteristics.

- Select the dressing that promotes a moist wound healing environment, controls exudate and protects peri-wound skin.
- If patient has pain with treatment, select a dressing that requires less frequent changes.
- For infected wounds, select a dressing that also decreases bacterial load.
- Details for use of negative pressure wound therapy including pressure settings are outlined in policy for this intervention - Negative Pressure Wound Therapy.

**Admission Criteria**

- Further medical evaluation needed
- Treatment and/or care requiring increased monitoring

**Discharge Criteria**

Patients should be discharged with a wound care plan outlining the best available options covered by their financial provider. The plan of care should detail the frequency of dressing changes, necessary supplies, caregiver providing the care, and location/service for follow up. Criteria to consider when discharging a patient are listed below.

- Overall patient condition
- Wound severity
- Patient care environment

**Consults/Referrals**

- Wound Ostomy Continence Nurses
- Plastic Surgery for stage III, stage IV or unstageable pressure ulcers as well as non-healing wounds and wounds that prompt concern for disfigurement
- Appropriate Surgical Service for surgical wounds
- Infectious Disease for infected wounds
- Nutrition Services
- Physical Therapy

**Follow-Up Care**

- A trained multidisciplinary group of experts should follow-up on patients.
- Home health services should be considered in patients with the following criteria
  - Severe wounds requiring negative pressure wound therapy or complicated treatment methods
  - Psychological concerns
  - Concerns related to access to follow-up including supplies
  - Need for DME care coordination

**Measures**

**Structure**

- Availability of a framework for consistent documentation

**Process**

- Percentage of multidisciplinary conferences for patients with chronic wounds (more than three months)
- Percentage of complete wound assessments documented at each dressing change

**Outcome**

- Percentage of patients with wounds classified as improving
- Percentage of patients with wounds classified as stalled
- Percentage of patients with wounds classified as deteriorating

Clinical Algorithm for Care of Acute and Chronic Wounds

Begin

Patient presents with a wound

Initial Assessment and Care
Assess wound and document characteristics
Cleanse wound with sterile saline
Redistribute pressure if necessary
Notify provider and/or physician of record

Inclusion Criteria
All TCH patients with acute and chronic wounds
Exclusion Criteria
Major Burns

Detailed Assessment by a WOCN, APP or physician
Document characteristics of the wound including measurement and volume
Assess for pain with and without treatment, signs of infection and percent of devitalized tissue
Determine etiology of wound
Initiate appropriate consults (see consult list on page 2)
Obtain a nutritional consult and initiate plan to correct any nutritional deficiencies

Obtain further consults as necessary to ensure a comprehensive plan for care
• vascular surgery for venous/arterial ulcers
• endocrine for diabetic foot ulcers
• plastic surgery for stage 3, 4 or unstaged pressure ulcers as well as non-healing wounds and wounds that prompt concern for disfigurement

Is this a non-healing chronic wound?
Yes
Debride necrotic tissue using most appropriate technique
Dry gangrene, heel wounds and eschar should be left in place until tissue revitalized

Select a dressing that promotes a moist healing environment, controls exudate and protects peri-wound skin
If patient has pain with treatment, select a dressing that requires less frequent changes.
(See Glossary of Wound Dressings)

Reassess wound at every dressing change
Note need for additional debridement and/or new dressing selection based upon wound characteristics
Document response to therapy

Inclusion Criteria
All TCH patient s with acute and chronic wounds
Exclusion Criteria
Major Burns

Obtain an x-ray of the affected area.
If additional imaging is needed, obtain a MRI
Obtain a bone biopsy
Consult Orthopedic Surgery

Is osteomyelitis suspected?
Yes

Obtain a nutritional consult and initiate plan to correct any nutritional deficiencies

If cellulitis present, see SSTI guideline
Consider topical antimicrobial
Consider ID consult
Select a dressing that promotes a moist wound healing environment, decreases bacterial load, controls exudate and protects peri-wound skin

Is infection suspected?
Yes
Culture wound via tissue biopsy. If tissue biopsy not available, use Levine technique to culture wound

Culture positive
Consult Orthopedic Surgery

Yes

Obtain additional imaging
Obtain further consults as necessary to ensure a comprehensive plan for care
• vascular surgery for venous/arterial ulcers
• endocrine for diabetic foot ulcers
• plastic surgery for stage 3, 4 or unstaged pressure ulcers as well as non-healing wounds and wounds that prompt concern for disfigurement

No

Is this a chronic wound?
Yes

Obtain a nutritional consult and initiate plan to correct any nutritional deficiencies

Obtain additional imaging
Obtain further consults as necessary to ensure a comprehensive plan for care
• vascular surgery for venous/arterial ulcers
• endocrine for diabetic foot ulcers
• plastic surgery for stage 3, 4 or unstaged pressure ulcers as well as non-healing wounds and wounds that prompt concern for disfigurement

No

Is infection suspected?
Yes
Culture wound via tissue biopsy. If tissue biopsy not available, use Levine technique to culture wound

Culture positive
Consult Orthopedic Surgery

No

Is this a chronic wound?
Yes

Obtain a nutritional consult and initiate plan to correct any nutritional deficiencies

Obtain further consults as necessary to ensure a comprehensive plan for care
• vascular surgery for venous/arterial ulcers
• endocrine for diabetic foot ulcers
• plastic surgery for stage 3, 4 or unstaged pressure ulcers as well as non-healing wounds and wounds that prompt concern for disfigurement

No

Is infection suspected?
Yes
Culture wound via tissue biopsy. If tissue biopsy not available, use Levine technique to culture wound

Culture positive
Consult Orthopedic Surgery

No

Is this a non-healing chronic wound?

Debride necrotic tissue using most appropriate technique
Dry gangrene, heel wounds and eschar should be left in place until tissue revitalized

Select a dressing that promotes a moist healing environment, controls exudate and protects peri-wound skin
If patient has pain with treatment, select a dressing that requires less frequent changes.
(See Glossary of Wound Dressings)

Reassess wound every 2 weeks of post initial presentation

Signs of wound healing noted within two weeks of initial presentation

If no signs of healing noted within 2 weeks of initial presentation
Reevaluate wound
Consider obtaining a surgical consultation
Consider an antimicrobial dressing or topical agent
Reassess nutritional status

Continue to current plan of care with continuous reassessment of need for modifications in dressing type or debridement

Yes

No

No

Yes

Yes

Yes

Yes
### Acute Wounds
- Follow a systematic approach to healing.

### Chronic Wounds
- Classified as vascular injuries (such as venous or arterial ulcers), pressure ulcers or diabetic wounds.
- Characteristics include prolonged inflammation of the wound bed and delayed healing.

### Non-Healing Wounds
- Classified as wounds that show no evidence of healing after 2 – 4 weeks of treatment. Practitioner should assess wound volume, dimensions, exudate and tissue type.

### High Risk Populations
- Patients with a history of trauma
- Patients with spinal cord injuries
- Patients with a fractured hip
- Acutely ill patients
- Patients with diabetes
- Patients in critical care
- Patients with surgical operative time greater than four hours

### Consultations
- Wound Ostomy Continence Nurse
- Plastic Surgery for stage 3, stage 4 or unstageable pressure ulcers as well as non-healing wounds and wounds that prompt concern for disfigurement.
- Appropriate surgical service for surgical wounds
- Infectious Disease for infected wounds
- Nutrition Services
- Physical Therapy
- Orthopedic Surgery for suspected Osteomyelitis
- For bone biopsy, consult Orthopedic Surgery or IR

### Wound Assessment Documentation
- Wound bed characteristics including percentage of granulation tissue and devitalized tissue
- Wound Measurement

### Debridement
- Utilize surgical debridement for infected wounds and/or wounds with a large amount of necrotic tissue.
- Autolytic debridement with appropriate dressings should be used for wounds without an urgent need for removal of devitalized tissue or infection.

### Pressure Redistribution
- Consider using a dynamic or specialist support surface appropriate for size and development of child

### Nutrition
- Consider a nutritional assessment by a dietician in the high risk population or patients with nonhealing wounds. Correct any identified nutritional deficiencies if appropriate for overall care.

### Signs of Wound Infection
- Lack of sign of healing for two weeks
- Friable granulation tissue
- Increased pain, redness, heat or exudate
- Infectious change in exudate characteristic (e.g. foul odor, purulent)
- Increase in the amount of necrotic tissue
- Pocketing, tunneling and/or bridging in the granulation tissue

### Wound Culture / Biopsy

#### Levine Technique
- Cleanse the wound with sterile saline
- Rotate the end of the swab over a 1cm² area for 5 seconds with enough pressure to extract exudate from wound tissue.

#### Biopsy
- Consultation with Orthopedic Surgery or Interventional Radiology needed for Bone Biopsy
References

Clinical Standards Preparation
This clinical standard was prepared by the Evidence-Based Outcomes Center (EBOC) team in collaboration with content experts at Texas Children's Hospital. Development of this clinical standard supports the TCH Quality and Patient Safety Program initiative to promote clinical standards and outcomes that build a culture of quality and safety within the organization.

Wound Care Guideline Content Expert Team
Claire Bocchini, MD, Infectious Disease
Edward Buchanan, MD, Plastic Surgery
Sara Engelhaup, RN, Nursing
Christina Franklin, RN, Nursing

Development Process
This clinical standard was developed using the process outlined in the EBOC Manual. The literature appraisal documents the following steps:

1. Review Preparation
   - PICO questions established
   - Evidence search confirmed with content experts

2. Review of Existing External Guidelines
   - Guideline for Prevention and Management of Pressure Ulcers, Wound, Ostomy and Continence Nurses Society, 2016;
   - Neonatal Skin Care, Association of Women's Health, Obstetric and Neonatal Nurses, 2013;
   - Prevention and Treatment of Pressure Ulcers: Clinical Practice Guideline, National Pressure Ulcer Advisory Panel, 2014;
   - Pressure Ulcers: Prevention and Management, National Institute for Health and Care Excellence, 2014;
   - Wound Healing Society 2015 Update on Guidelines for Pressure Ulcers, Wound Healing Society, 2016;
   - The burn/wound guidelines-2: Guidelines for the diagnosis and treatment of pressure ulcers, Japanese Dermatological Association, 2011;
   - Evidence-based recommendations for the use of negative pressure wound therapy in chronic wounds:
   - Steps towards an international consensus, International Expert Panel on Negative Pressure Wound Therapy, 2011;
   - Guideline for the prevention of Surgical Site Infection, Centers for Disease Control and Prevention, 2017;
   - Wound Healing Society 2015 Update on Guidelines for Diabetic Foot Ulcers, Wound Healing Society, 2016;
   - Wound Healing Society 2015 Update on Guidelines for Venous Ulcers, Wound Healing Society, 2016;

3. Literature Review of Relevant Evidence
   - Searched: PubMed, Cinahl, Cochrane Library

4. Critically Analyze the Evidence
   - Twenty-two meta-analyses, twelve randomized controlled trials, and twenty-eight nonrandomized studies

5. Summarize the Evidence
   - Materials used in the development of the clinical standard, literature appraisal, and any order sets are maintained in a Wound Care evidence-based review electronic file.

Evaluating the Quality of the Evidence
Published clinical guidelines were evaluated for this review using the AGREE II criteria. The summary of these guidelines are included in the literature appraisal. AGREE II criteria evaluate Guidelines Scope and Purpose, Stakeholder Involvement, Rigor of Development, Clarity and Presentation, Applicability, and Editorial Independence using a 4-point Likert scale. The higher the score, the more comprehensive the guideline.

This clinical standard specifically summarizes the evidence in support of or against specific interventions and identifies where evidence is lacking/inconclusive. The following categories describe how research findings provide support for treatment interventions.

- “Evidence Supports” provides evidence to support an intervention
- “Evidence Against” provides evidence against an intervention
- “Evidence Lacking/Inconclusive” indicates there is insufficient evidence to support or refute an intervention and no conclusion can be drawn from the evidence.

The GRADE criteria were utilized to evaluate the body of evidence used to make practice recommendations. The table below defines how the quality of the evidence is rated and how a strong versus weak recommendation is established. The literature appraisal reflects the critical points of evidence.

<table>
<thead>
<tr>
<th>Quality</th>
<th>Type of Evidence</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Consistent evidence from well-performed RCTs or exceptionally strong evidence from unbiased observational studies</td>
</tr>
<tr>
<td>Moderate</td>
<td>Evidence from RCTs with important limitations (e.g., inconsistent results, methodological flaws, indirect evidence, or imprecise results) or unusually strong evidence from unbiased observational studies</td>
</tr>
<tr>
<td>Low</td>
<td>Evidence for at least 1 critical outcome from observational studies, RCTs with serious flaws or indirect evidence</td>
</tr>
<tr>
<td>Very Low</td>
<td>Evidence for at least 1 critical outcome from unsystematic clinical observations or very indirect evidence</td>
</tr>
</tbody>
</table>

Recommendations
Practice recommendations were directed by the existing evidence and consensus amongst the content experts. Patient and family preferences were included when possible. The Content Expert Team and EBOC team remain aware of the controversies in the management of wounds. When evidence is lacking, options in care are provided in the clinical standard and the accompanying order sets (if applicable).
**Approval Process**
Clinical standards are reviewed and approved by hospital committees as deemed appropriate for its intended use. Clinical standards are reviewed as necessary within EBOC at Texas Children’s Hospital. Content Expert Teams are involved with every review and update.

**Disclaimer**
Practice recommendations are based upon the evidence available at the time the clinical standard was developed. Clinical standards (guidelines, summaries, or pathways) do not set out the standard of care and are not intended to be used to dictate a course of care. Each physician/practitioner must use his or her independent judgment in the management of any specific patient and is responsible, in consultation with the patient and/or the patient’s family, to make the ultimate judgment regarding care.
