Enhancing Influenza Vaccine Knowledge and Confidence Among Residents

Lynda Aririguzo, MD, MPH, Linessa Zuniga, MD, Med, Andria Tatem, MD, Teresa Duryea, MD
Department of Pediatrics, Texas Children's Hospital, Baylor College of Medicine

Background

- The 2017-18 influenza season was of epidemic proportion. Many of the children who died were unvaccinated. Yet one third of parents interviewed prior to the 2018-2019 influenza season reported their children would not receive influenza vaccines.
- Pediatric residents may not be comfortable counseling vaccine hesitant families.
- Through a fellow-led QI project, we sought to provide educational interventions to increase pediatric residents' knowledge and confidence in counseling influenza vaccine hesitant families.
- The site for this project was the Texas Children's Hospital Primary Care Practice clinic, a continuity clinic for approximately 45 pediatric residents located outside of the medical center in an underserved area of Houston.

Aim/Objective

- Within a 7 month period, through educational interventions:
- Increase the percentage of residents who give a favorable rating of their perceived knowledge of resources for influenza vaccine hesitant parents to 85%
- Increase the percentage of residents who give a favorable rating of their confidence in addressing parents' concerns about the influenza vaccine to 85%

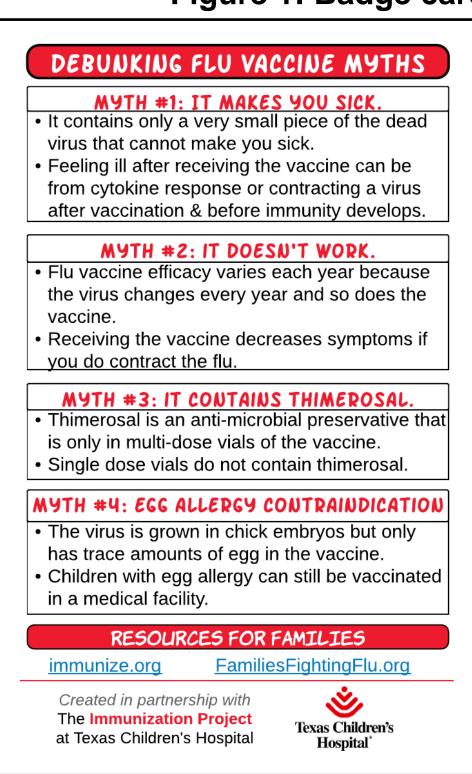

Methods

- Baseline data was obtained via anonymous online surveys to measure pediatric residents' confidence and perceived knowledge of resources.
- We defined a favorable rating for perceived knowledge of resources as "average", "above average", or "excellent".
- We defined a favorable rating for confidence in addressing parents' concerns about the influenza vaccine as "very confident" or "extremely confident".
- PDSA Cycle 1
 - Residents participated in fellow-led educational sessions that discussed vaccine manufacturing, adverse effects and common myths.
 - The CASE method, a resource to improve counseling skills toward vaccine hesitant families, was introduced. Badge cards were distributed with facts debunking common myths and an outline of the CASE method.
 - Residents participated in a role play activity to practice counseling.

PDSA Cycle 2

 In a second educational session, the role play activity was modified to facilitate increased interaction and provide feedback on counseling techniques.

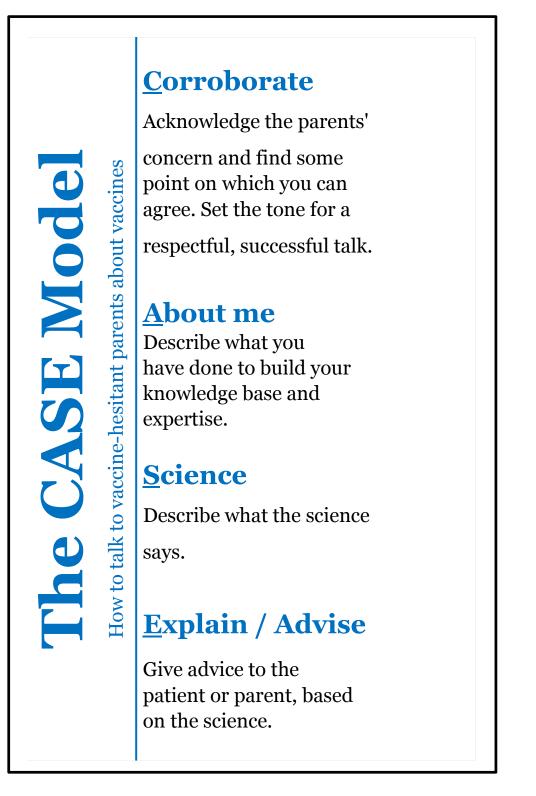

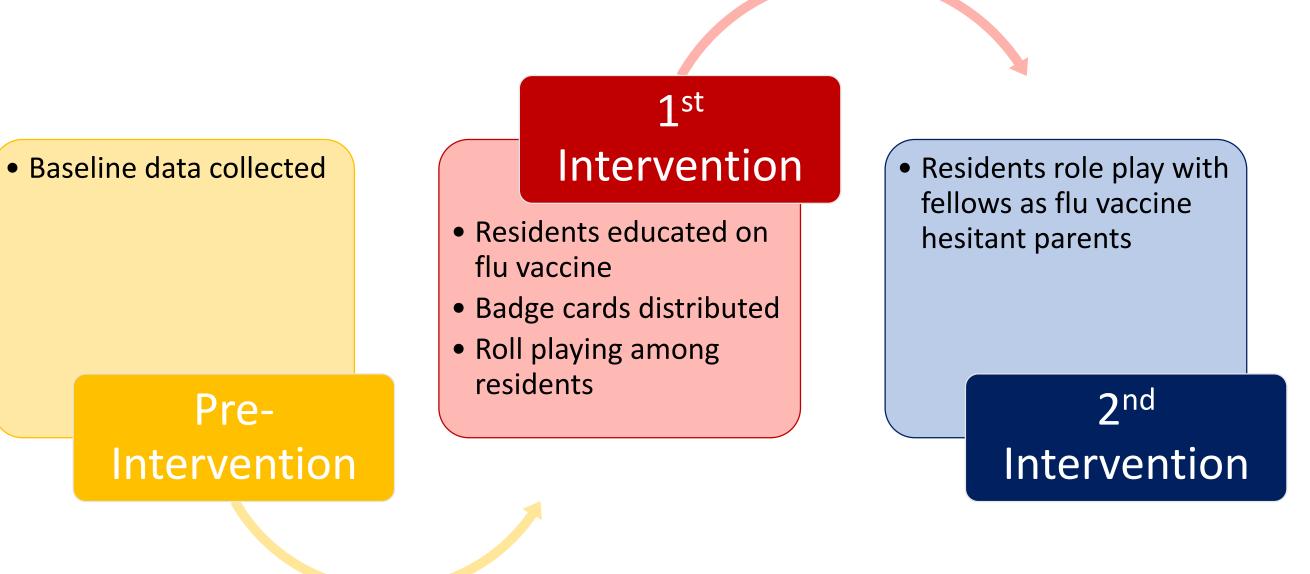

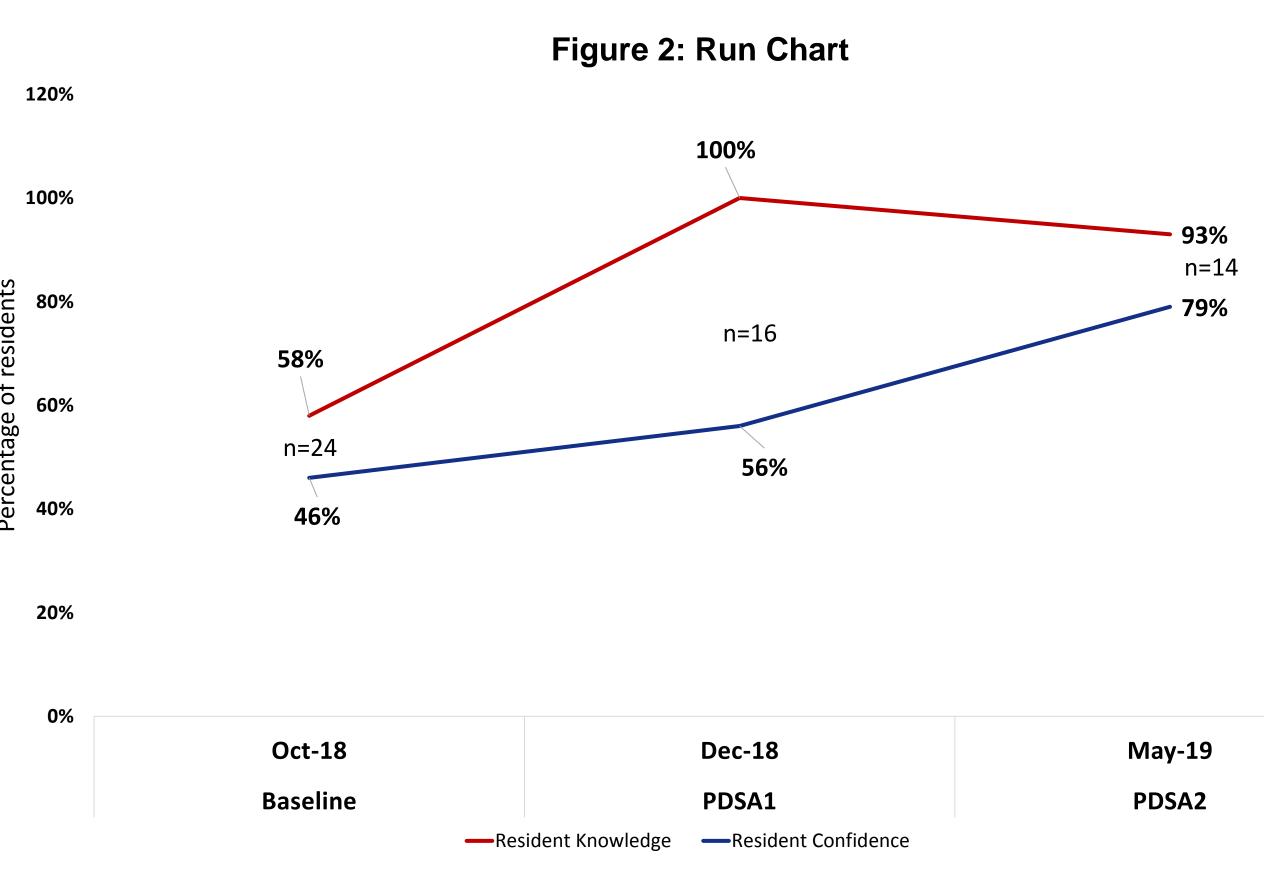

Figure 2: Interventions implemented

Results

 Overall, self-reported resident knowledge about resources for influenza vaccine hesitant parents increased by 35%. Self-reported resident confidence in counseling parents increased by 22% overall.

Conclusion

- Providing interactive education and reference tools regarding influenza vaccine and guided counseling for vaccine hesitant families can increase residents' knowledge and confidence in counseling parents who are influenza vaccine hesitant.
- Future plans to apply this same education to residents in counseling for general vaccine hesitancy is also being considered.
