

Peritoneal Dialysis

One type of dialysis is called peritoneal dialysis. Peritoneal dialysis removes the waste (bad things) in your body by using special fluid that works like a magnet to grab the bad things, and take them out of your body.

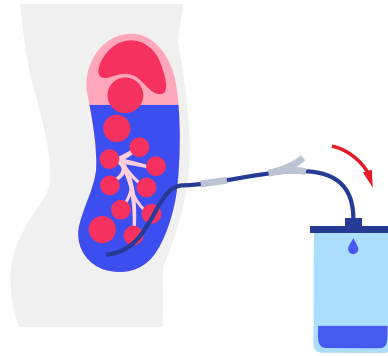

Step 1

The dialysis solution flows through the tube and catheter into the peritoneal cavity.

Step 2

Dialysis solution absorbs waste and extra fluids from the body.

Step 3

Draining the fluid.

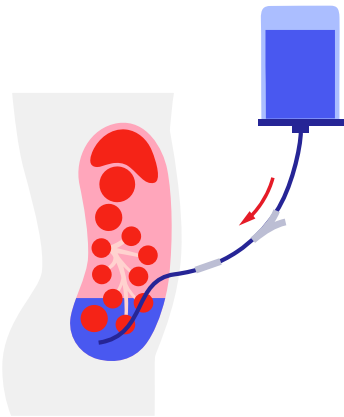

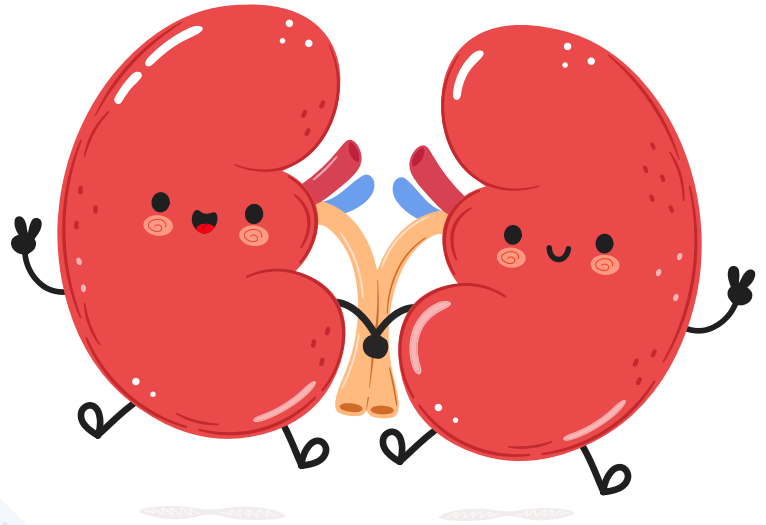

During peritoneal dialysis, fluid is put into your tummy through a special tube. The fluid sits in your belly and attracts all of the waste in your body. When the fluid drains out of your tummy, the waste goes with it. This will happen multiple times until the waste is out of your body.

You do peritoneal dialysis at home, while you sleep! When you wake up and your dialysis is over, the tubes are unhooked and you can leave your room to play!
